## Qualitative Analysis of Critical Points

## More Precise Definition of Stability (after Dirichlet)

"The equilibrium [of a mechanical system] is **stable** if, in displacing the points of the system **from their equilibrium positions** by an **infinitesimal amount** and giving each one a **small initial velocity**, the displacements of different points of the system remain, **throughout the course of the motion**, contained within **small** prescribed limits"

## Consequences of Dirichlet's Definition

- (1) Stability is a quality of **each equilibrium solution** (We cannot generally state *a priori* that a system, **as a whole**, is stable or unstable)
- (2) The problem of ascertaining the stability of a solution concerns the **neighborhood of that solution** and is therefore a **local one**
- (3) The concept of stability is inherently **dynamic** in nature. But for conservative systems, dynamics can be "**factored out**" of the problem, and we are left with **static** criteria

## Goal of Chapter

**Qualitative *classification* of bifurcation and limit points  
as regards *global & post critical behavior* - focus on  
energetic interpretation resembling rolling ball**

**No equations - all pictures**

## **Assumptions & Limitations**

**In this and following 2 Chapters we will **not neglect changes in geometry****

**However, we still confine attention to **conservative systems****

**Their stability can be analyzed by **static criteria**,  
in particular the **tangent stiffness spectrum****

## General Procedure

Run a **geometrically nonlinear** analysis, getting the control vs state response

Look for **critical points** but keep going (traverse them)

Examine the **spectrum** of the tangent stiffness matrix as CPs are traversed

## Classification of Equilibrium Configurations as per Spectrum of Tangent Stiffness $K$ There

<i>If <math>K</math> evaluated at an <b>equilibrium position</b> is</i>	<i>The potential energy <math>\Pi</math> at that position has a</i>	<i>Then the <b>equilibrium position</b> is</i>
positive definite	strict minimum	stable
positive semidefinite*	cylindrical or inflexion point	neutrally stable
indefinite	saddle point	unstable

\* also known as nonnegative

It is sufficient to apply this test at just **one point between CPs** to declare the whole path stable or unstable - Why?

## Qualitative Approach to Stability

Instead of mathematics we can take a **qualitative** look at stability loss at **various types of critical points** using a physical **analogy**:

A "rolling ball" over ground under action of **gravity**, mapped to a **potential energy function** interpretation

Several examples of applications of this visualization technique will be given

## Recall the Picture for the Little Kids

For the grown ups we map

**Gravity** → **Potential Energy**

# Stability Exchange at a Limit Point (1 DOF)

## Stability Exchange at a Limit Point (2 DOF)

# Asymmetric Bifurcation

# Stable-Symmetric Bifurcation

# Unstable-Symmetric Bifurcation

## **Next Two Chapters Deal With the Mathematical Models**

**Chapter 33: nonlinear stability analysis levels**

**Chapter 34: effect of imperfections**
